# Formal Definition of a NFA

An **NFA** is a 5-tuple  $M = (Q, \Sigma, \delta, q_0, F)$

$Q$  is the set of states

$\Sigma$  is the alphabet

$\delta : Q \times \Sigma_\epsilon \rightarrow P(Q)$  is the transition function

$q_0 \in Q$  is the start state

$F \subseteq Q$  is the set of accept states

$M$  **accepts** a string  $w$  if **there exists** a path from  $q_0$  to an accept state that can be followed by reading  $w$ .

# DFAs vs. NFAs

## Deterministic Computation

**accept or reject**

## Nondeterministic Computation

### *Ways to think about nondeterminism*

- (restricted) parallel computation
- tree of possible computations
- guessing and verifying the “right” choice

# Are NFAs more powerful than DFAs?

- There exist languages which require strictly more states to recognize with DFA than with NFA.
- Are there languages that can be recognized by an NFA and still cannot be recognized by *any* DFA (with any # of states)?

# Are NFAs more powerful than DFAs?

- There exist languages which require strictly more states to recognize with DFA than with NFA.
- Are there languages that can be recognized by an NFA and still cannot be recognized by *any* DFA (with any # of states)?

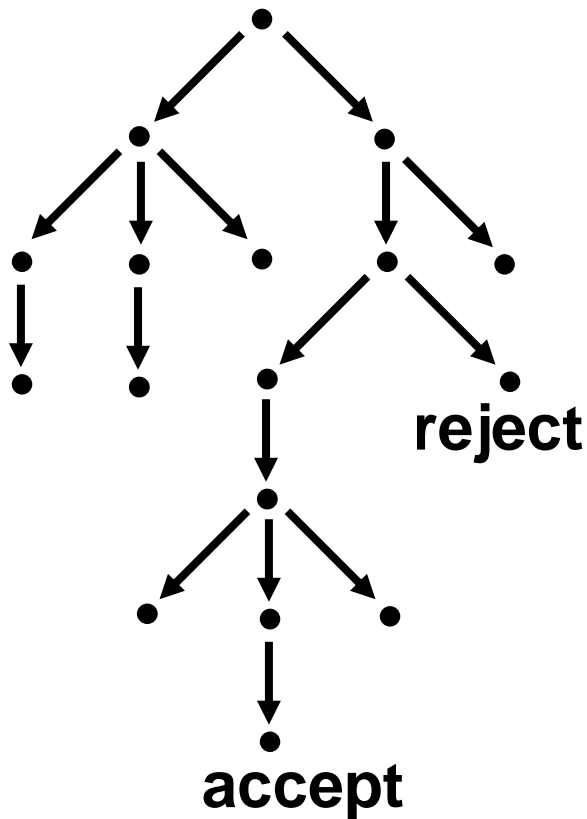

**Theorem:** For every NFA  $N$ , there is a DFA  $M$  such that  $L(M) = L(N)$

**Corollary:** A language is regular if and only if it is recognized by an NFA

# Equivalence of NFAs and DFAs (Proof)

Let  $N = (Q, \Sigma, \delta, q_0, F)$  be an NFA

Goal: Construct DFA  $M = (Q', \Sigma, \delta', q_0', F')$  recognizing  $L(N)$

**Intuition:** Run all threads of  $N$  in parallel, maintaining the set of states where all threads are.

# Equivalence of NFAs and DFAs (Proof)

Let  $N = (Q, \Sigma, \delta, q_0, F)$  be an NFA

Goal: Construct DFA  $M = (Q', \Sigma, \delta', q_0', F')$  recognizing  $L(N)$

**Intuition**: Run all threads of  $N$  in parallel, maintaining the set of states where all threads are.

**More precisely**:

$$Q' = P(Q)$$

$$\delta'(q', \sigma) = q'', \text{ where}$$

$$q'' = \{q \in Q \mid q \text{ is reachable from a state } r \in q'\}$$

by either reading  $\sigma$ , or an  $\epsilon$  move}

$$\text{Or in other words: } q'' = \bigcup_{r \in q'} \{q \mid \delta(r, \sigma) = q\}$$

$$q_0' = \{q_0\}, \quad F' = \{r \subseteq Q \mid r \text{ contains a state } q \in F\}$$

$$\{\epsilon(q_0)\}$$

# Proving the Construction Works

9. Via 0 or more  $\epsilon$  moves

**Claim:** For every string  $w$ , running  $M$  on  $w$  leads to state

$\{q \in Q \mid \text{There exists a computation of } N \text{ on input } w \text{ ending at } q\}$

**Proof idea:** “By construction”

More formally, by induction on  $|w|$ .

# NFA -> DFA Example

NFA!

DFA! states:  $\{\emptyset\}$ ,  $\{a\}$ ,  $\{b\}$ ,  $\{a,b\}$

$\delta'$	0	1
$\emptyset$	$\emptyset$	$\emptyset$
$a$	$\emptyset$	$b$
$b$	$\emptyset$	$\emptyset$
$a,b$	$\emptyset$	$\emptyset$
$\emptyset$	$\emptyset$	$\emptyset$

$$q'_0 = \{a\}$$

$$F' = \{\emptyset\}, \{a,b\}$$

# NFA -> DFA Example

NFA!

DFA!

$\delta'$	0	1
$\emptyset$	$\emptyset$	$\emptyset$
$\{1\}$	2	$\{2,3\}$
$\{2\}$	$\{2,3\}$	2
$\{3\}$	$\emptyset$	$\emptyset$
$\{1,2\}$	$\{2,3\}$	$\{2,3\}$
$\{2,3\}$	$\{2,3\}$	$\{2,3\}$
$\{1,3\}$	$\{2,3\}$	$\{2,3\}$
$\{1,2,3\}$	$\{2,3\}$	$\{2,3\}$

# Can we make the blowup in # states smaller?

Subset construction converts an  $n$  state NFA into a  $2^n$ -state DFA

Could there be a construction that always produces, say, an  $n^2$ -state DFA?

**Theorem:** For every  $n \geq 1$ , there is a language  $L_n$  such that

1. There is an  $(n + 1)$ -state NFA recognizing  $L_n$ .
2. There is no DFA recognizing  $L_n$  with fewer than  $2^n$  states.

**Conclusion:** For finite automata, nondeterminism provides an exponential savings over determinism (in the worst case).

# What does class of regular languages look like?

- We saw that it's a pretty robust set of languages...

(  $L(\text{NFAs}) = L(\text{DFAs})$  )

- What about closure with respect to natural operations?

# - Regular Operations

# An Analogy *(can ignore...)*

In algebra, we try to identify operations which are common to many different mathematical structures

**Example:** The integers  $\mathbb{Z} = \{\dots - 2, -1, 0, 1, 2, \dots\}$  are **closed** under

- Addition:  $x + y$
- Multiplication:  $x \times y$
- Negation:  $-x$
- ...but **NOT** Division:  $x / y$

We'd like to investigate similar closure properties of the **class of regular languages**

# Regular operations on languages

Let  $A, B \subseteq \Sigma^*$  be languages. Define

**Union:**  $A \cup B = \{x \mid x \in A \vee x \in B\}$

**Concatenation:**  $A \circ B = \{xy \mid x \in A, y \in B\}$

$$A^n = \{x_1 \dots x_n \mid \forall i, x_i \in A\}$$

**Star:**  $A^* = \bigcup_{n \in \mathbb{N}} A^n$

# Other operations

Let  $A, B \subseteq \Sigma^*$  be languages. Define

**Complement:**  $\bar{A} = \{x \mid x \notin A\}$

**Intersection:**  $A \cap B = \{x \mid x \in A \wedge x \in B\}$

**Reverse:**  $A^R = \{x_1 \dots x_n \mid x_i \in \Sigma, \wedge x_n \dots x_1 \in A\}$

# Closure properties of the regular languages

**Theorem:** The class of regular languages is **closed** under all three regular operations (union, concatenation, star), as well as under complement, intersection, and reverse.

i.e., if  $A$  and  $B$  are regular, applying any of these operations yields a regular language

# Proving Closure Properties

# Complement

Complement:  $\bar{A} = \{w \mid w \notin A\}$

**Theorem:** If  $A$  is regular, then  $\bar{A}$  is also regular

Proof idea:

- all accepting states become non-accepting
- all non-accepting states become accepting

$$F' = Q \setminus F$$

# Union

Union:  $A \cup B = \{ w \mid w \in A \text{ or } w \in B \}$

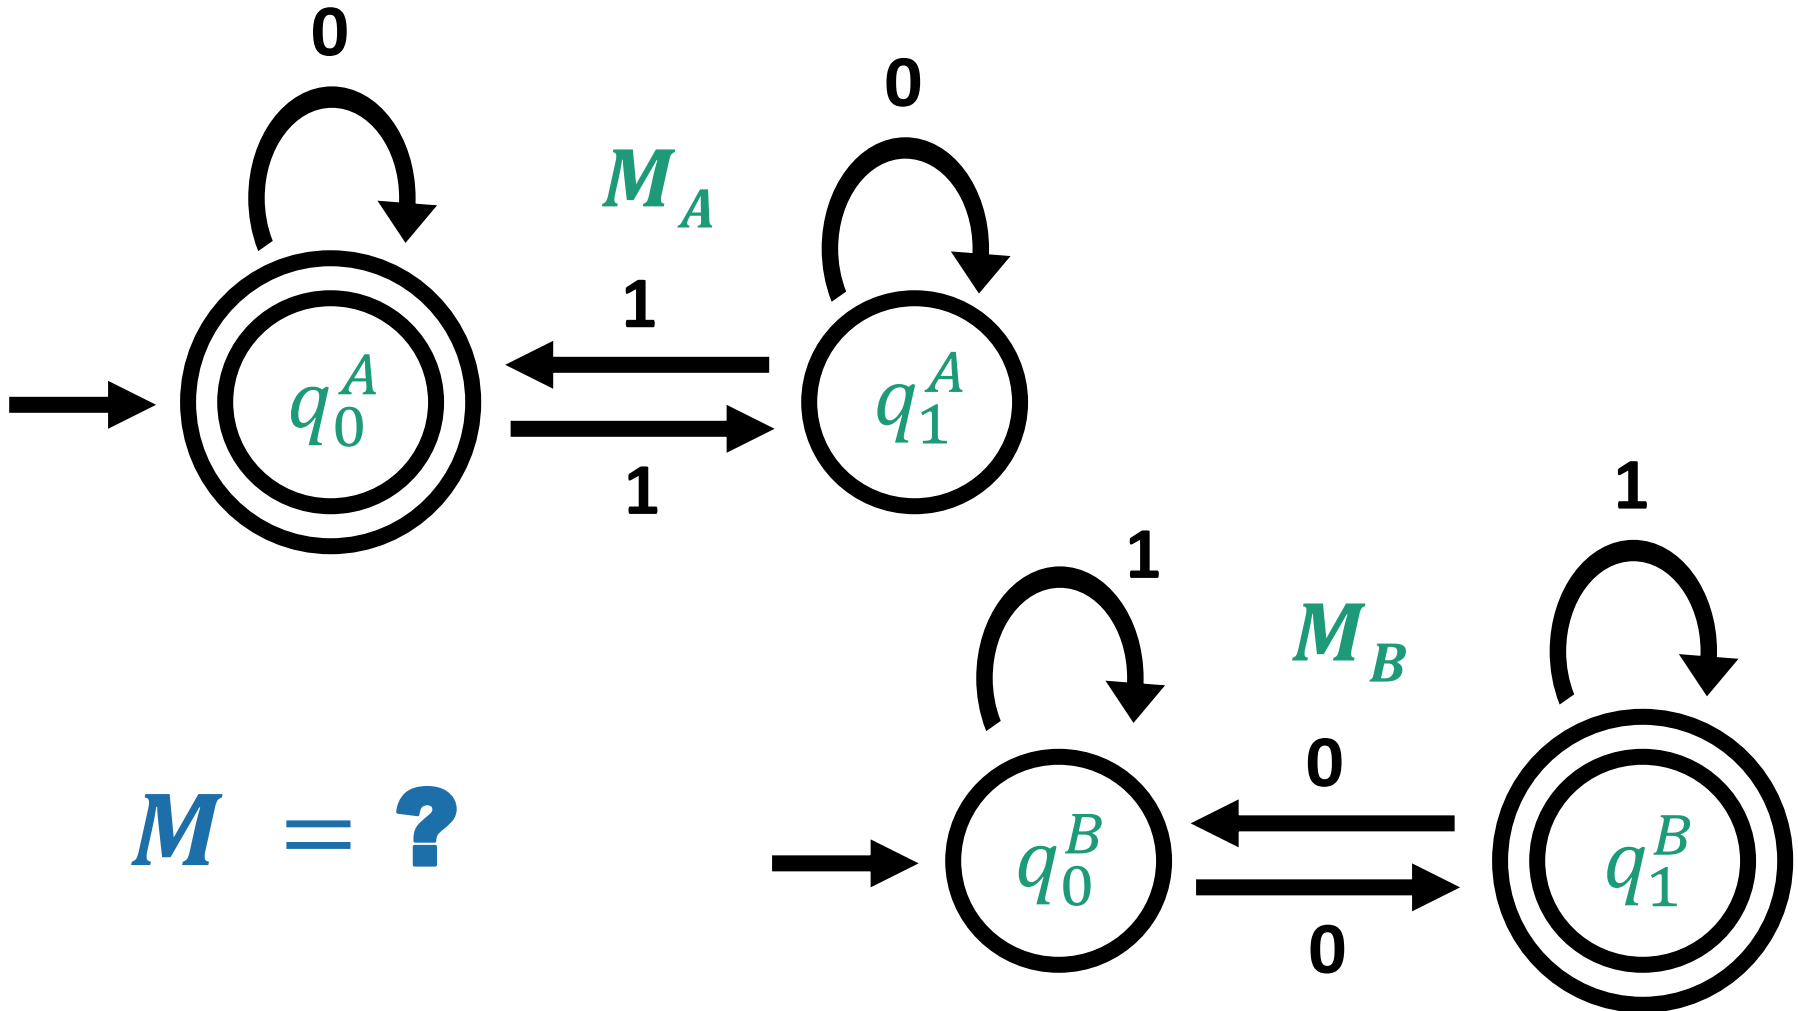

**Theorem:** If  $A$  and  $B$  are regular, then so is  $A \cup B$

**Proof:**

Let  $M_A = (Q_A, \Sigma, \delta_A, q_0^A, F_A)$  be a DFA recognizing  $A$  and  
 $M_B = (Q_B, \Sigma, \delta_B, q_0^B, F_B)$  be a DFA recognizing  $B$

Goal: Construct a DFA  $M = (Q, \Sigma, \delta, q_0, F)$   
that recognizes  $A \cup B$

# Example

# Intersection

Intersection:  $A \cap B = \{w \mid w \in A \text{ and } w \in B\}$

**Theorem:** If  $A$  and  $B$  are regular, then so is  $A \cap B$

**Proof:**

Let  $M_A = (Q_A, \Sigma, \delta_A, q_0^A, F_A)$  be a DFA recognizing  $A$  and  
 $M_B = (Q_B, \Sigma, \delta_B, q_0^B, F_B)$  be a DFA recognizing  $B$

Goal: Construct a DFA  $M = (Q, \Sigma, \delta, q_0, F)$   
that recognizes  $A \cap B$

# Intersection

Intersection:  $A \cap B = \{w \mid w \in A \text{ and } w \in B\}$

**Theorem:** If  $A$  and  $B$  are regular, then so is  $A \cap B$

**Another Proof:**

$$A \cap B = \overline{\overline{A} \cup \overline{B}}$$

# Operations on languages

Let  $A, B \subseteq \Sigma^*$  be languages. Define

Regular Operations  $\left\{ \begin{array}{l} \text{Union: } A \cup B \\ \text{Concatenation: } A \circ B = \{ab \mid a \in A, b \in B\} \\ \text{Star: } A^* = \{a_1 a_2 \dots a_n \mid n \geq 0 \text{ and } a_i \in A\} \end{array} \right.$

Complement:  $\bar{A}$

Intersection:  $A \cap B$

Reverse:  $A^R = \{a_1 a_2 \dots a_n \mid a_n \dots a_1 \in A\}$

**Theorem:** The class of regular languages is **closed** under all six of these operations

# Closure under Reverse

**Theorem.** The reverse of a regular language is also regular

**Proof:** Let  $L$  be a regular language and  $M$  be a DFA recognizing it. Construct an NFA  $M'$  recognizing  $L^R$ :

- Define  $M'$  as  $M$  with the arrows reversed.
- Make the start state of  $M$  be the accept state in  $M'$ .
- Make a new start state that goes to all accept states of  $M$  by  $\epsilon$ -transitions.

# Closure under Concatenation

Concatenation:  $A \circ B = \{ ab \mid a \in A \text{ and } b \in B \}$

**Theorem.** If  $A$  and  $B$  are regular,  $A \circ B$  is also regular.

**Proof:** Given DFAs  $M_A$  and  $M_B$ , construct NFA by

- Connecting all accept states in  $M_A$  to the start state in  $M_B$ .
- Make all states in  $M_A$  non-accepting.

# Closure under Concatenation

Concatenation:  $A \circ B = \{ ab \mid a \in A \text{ and } b \in B \}$

**Theorem.** If  $A$  and  $B$  are regular,  $A \circ B$  is also regular.

**Proof:** Given DFAs  $M_A$  and  $M_B$ , construct NFA by

- Connecting all accept states in  $M_A$  to the start state in  $M_B$ .
- Make all states in  $M_A$  non-accepting.

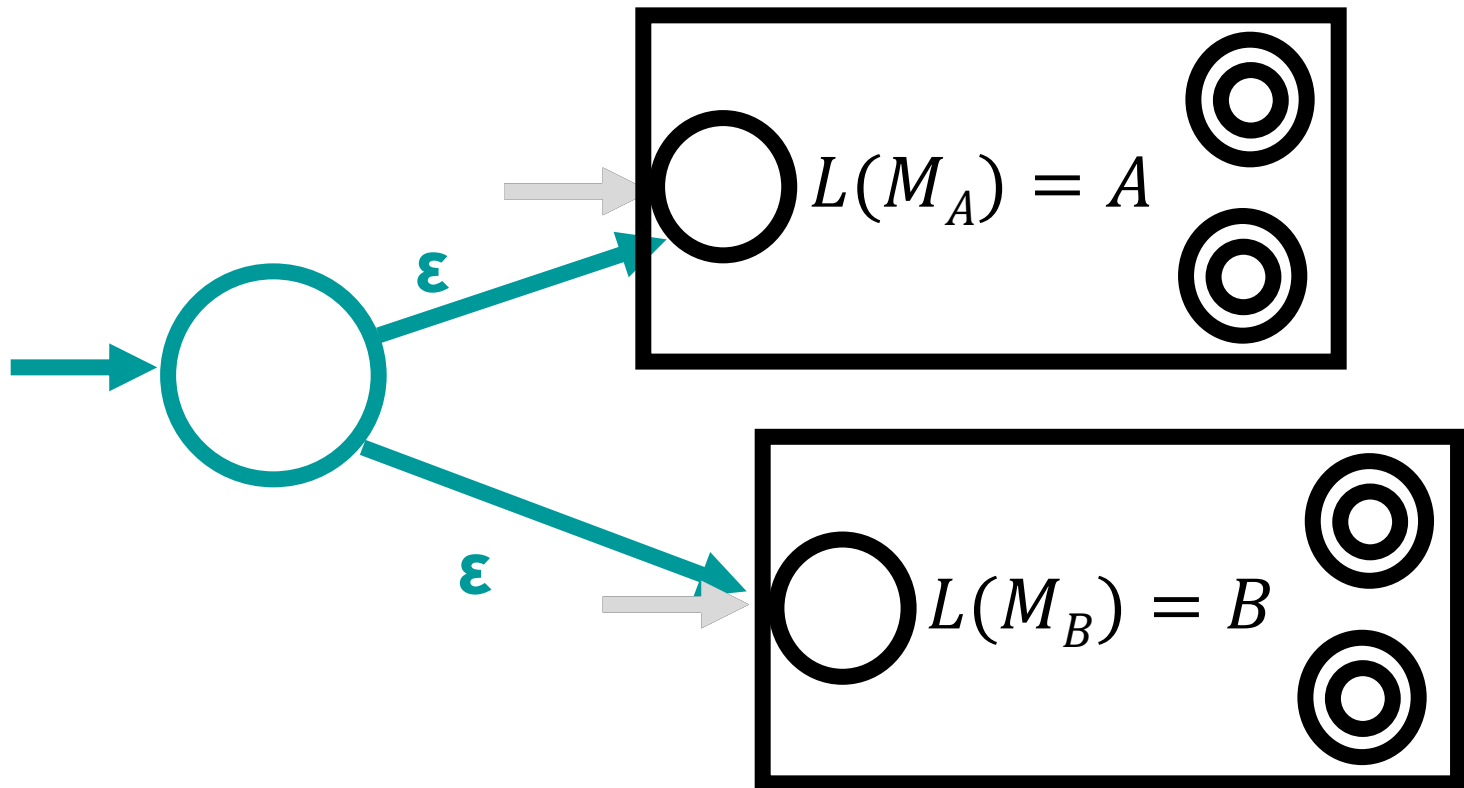

Question: What happens if we <sup>instead</sup> verify the starting states of B with the ~~non~~ accepting states of A?

# A Mystery Construction

Given DFAs  $M_A$  recognizing  $A$  and  $M_B$  recognizing  $B$ , what does the following NFA recognize?

# Closure under Star

Star:  $A^* = \{ a_1 a_2 \dots a_n \mid n \geq 0 \text{ and } a_i \in A \}$

**Theorem.** If  $A$  is regular,  $A^*$  is also regular.

# Closure under Star

Star:  $A^* = \{ a_1 a_2 \dots a_n \mid n \geq 0 \text{ and } a_i \in A \}$

**Theorem.** If  $A$  is regular,  $A^*$  is also regular.
